## Lecture 4

## Balanced Motion Part 2

### 4.1 The Gradient Wind

The gradient wind is defined as the wind existing if the trajectory of a particle (or air parcel) is circular and we have a balance among the pressure gradient force, the Coriolis force and the centrifugal force.

## A. Cyclonic flow (low pressure)

In this case, a Coriolis force and the centrifugal force act in the same direction. In order to have a balance, the pressure gradient force must act in the opposite direction and we have a low pressure in the center (see case a in Figure 4.1).

If we take the effect of curvature into account, we have to expand the horizontal momentum equation to include the centrifugal term:

$$
\begin{equation*}
P G F=C F+C e F \tag{4.1}
\end{equation*}
$$

and by using geostrophic balance $f V_{g}=-\frac{1}{\rho} \frac{\partial p}{\partial n}$, equation 4.1 becomes:

$$
\begin{equation*}
\mathrm{f} \mathrm{~V}_{\mathrm{g}}=\mathrm{f} \mathrm{~V}_{\mathrm{G}}+\frac{\mathrm{V}_{\mathrm{G}}^{2}}{\mathrm{R}} \tag{4.2}
\end{equation*}
$$

Here R is the radius of curvature. $\mathrm{V}_{\mathrm{G}}$ is the Gradient wind.

Fig. 4.1
Four balances in the Northern Hemisphere for the four types of gradient flow.

P is the pressure gradient force (PGF)
Co is Coriolis force (CF)
Ce is the centrifugal force
H is short of High, L short of Low

The gradient wind speed is obtained by solving equation (4.2) for $V_{G}$ to yield:

$$
\mathrm{f} \mathrm{~V}_{\mathrm{g}}=\mathrm{f} \mathrm{~V}_{\mathrm{G}}+\frac{\mathrm{V}_{\mathrm{G}}^{2}}{\mathrm{R}}
$$

Dividing by $V_{G}^{2}$,

$$
\begin{gathered}
f \frac{V_{g}}{V_{G}^{2}}=\frac{f}{V_{G}}+\frac{1}{R} \\
f V_{g}\left(\frac{1}{V_{G}}\right)^{2}-f\left(\frac{1}{V_{G}}\right)-\frac{1}{R}=0
\end{gathered}
$$

By using quadratic formula to solve,

$$
x=\frac{b \mp \sqrt{b^{2}+4 a c}}{2 a}
$$

we get,

$$
\begin{gathered}
a=f V_{g} \quad b=f \quad c=\frac{1}{R} \quad x=\frac{1}{V_{G}} \\
\frac{1}{V_{G}}=\frac{f \mp \sqrt{f^{2}+4 \frac{f V_{g}}{R}}}{2 f V_{g}}
\end{gathered}
$$

Dividing the numerator and the denominator of the right side on $(2 f)$ we get,

$$
\begin{aligned}
\frac{1}{V_{G}} & =\frac{\frac{1}{2} \mp \sqrt{\frac{1}{4}+\frac{V_{g}}{R f}}}{V_{g}} \\
\therefore \quad V_{G} & =\frac{V_{g}}{\frac{1}{2} \mp \sqrt{\frac{1}{4}+\frac{V_{g}}{R f}}}
\end{aligned}
$$

This equation tells us that $V_{G}<V_{g}$ in all cases because the denominator is larger than one. The difference between $V_{G} \& V_{g}$ becomes larger at smaller R , and at smaller $f$. To illustrate this difference we consider:

$$
\begin{equation*}
\text { At } \quad V_{g}=10 \frac{m}{s} \quad \text { and } \quad f=10^{-4} \mathrm{~s}^{-1} \tag{2-4}
\end{equation*}
$$

if $R=1000 \mathrm{~km}$, we find $V_{G}=9.16 \mathrm{~m} / \mathrm{s}$ and the difference between $V_{G} \& V_{g}$ is small.

When R becomes much smaller the difference between $V_{G} \& V_{g}$ will be large.
If we assume that $f=10^{-4} \mathrm{~s}^{-1}$ and $V_{g}=10 \frac{\mathrm{~m}}{\mathrm{~s}}$ we may calculate the value of R necessary to make $V_{G}=\frac{1}{2} V_{g}$, we find from the equation that the radius of $R=$ 200 km

## B. Anticyclonic flow (high pressure)

In this case, a pressure gradient force and the centrifugal force are in the same direction. In order to have a balance the Coriolis force must act in the opposite direction, we have a high pressure in the center (case b and din Fig. 4.1).

$$
\begin{gathered}
P G F+C e F-C F=0 \\
f V_{g}+\frac{V_{G}^{2}}{R}-f V_{G}=0
\end{gathered}
$$

In the same previous manner,

$$
\therefore \quad V_{G}=\frac{V_{g}}{\frac{1}{2}+\sqrt{\frac{1}{4}-\frac{V_{g}}{R f}}}
$$

We see that $V_{G}>V_{g}$ in all cases.
In the special case where $\frac{V_{g}}{R f}=\frac{1}{4}, V_{G}=2 V_{g}$, the maximum wind in the anticyclonic case is therefore twice the geostrophic wind. If we assume that, $f=10^{-4} \mathrm{~s}^{-1}$ and $V_{g}=10 \mathrm{~m} / \mathrm{s}$, the radius of curvature is equal to 400 km , and thus quite small.

### 4.2The Cyclostrophic Flow

Cyclostrophic balance occurs when the pressure gradient force and centrifugal force are equal and in opposite direction. This is the situation near the equator

$$
G F=C e F
$$

$f V_{g}=\frac{V_{G}^{2}}{R}$
$V_{G}^{2}=f V_{g} R$
$\therefore \quad V_{G}=\sqrt{f V_{g} R}$

### 4.3 The Inertial Flow

In inertial flow, there is no pressure gradient force, there are two forces only,
Coriolis and centrifugal that may balance each other.
$C F=C e F$
$f V_{G}=\frac{V_{G}^{2}}{R}$
$V_{G}=R f$
