

(This summary is designed only for the lecture; it never designed for any exam.)

CLINICAL PHARMACOKINETIC FOR AMINOGLYCOSIDE:

A-Initial dose determination.

B-Use of Aminoglycoside concentration to change the dose.

Initial dose determination:

- 1- pharmacokinetic dosing method.
- 2-Hull and Sarubbi nomogram method.
- 3-Harford nomogram method for extended interval dosing.
- 4-Literature-based recommended dosing method

1-Pharmacokinetic dosing methods

To get the initial dose using pharmacokinetic dosing method, the following should be known:

1- The actual weight of the patient and its relation to ideal body weight.

$\% \text{ overweight} = \frac{(ABW - IBW)}{IBW} \times 100\%$, **ABW**= Actual body weight, **IBW**= Ideal body weight

IBW (male) = 50 + 2.3 (H - 60) IBW (female) = 45.5 + 2.3 (H - 60)

Where: H = *height in inches*

IBW (male) = 0.9 H – 88 IBW (female) = 0.9 H – 92

Where: H = *height in centimeters*

2-Creatinine clearance

A- If the patient has stable renal function and not obese, use Cockcroft and Gault EQ:

$$CrCl_{male} = \frac{(140 - Age) * wt}{72 * Sc}$$

$$CrCl_{female} = 0.85 \frac{(140 - Age) * wt}{72 * Sc}$$

(Cockcroft and Gault) where Age in years, Wt in Kg, and Sc in mg/dL.

B- If the patient has stable renal function and obese (above 30% of its ideal body weight), use Salazar and Corcoran equation:

$$CrCl_{male} = \frac{(137 - age)[(0.285 * Wt) + (12.1 * Ht^2)]}{(51 * sc)}$$

$$CrCl_{female} = \frac{(146 - age)\{(0.287 * Wt) + (9.74 * Ht^2)\}}{(60 * sc)}$$

where Age in years, Wt in Kg, Ht in meter, and Sc in mg/dL.

Note: Inch= 2.54 cm

3- The volume of distribution of Aminoglycoside in the patient

Adult, normal renal fun	0.26 L/kg
Adult, renal failure	0.26 L/kg
burn	0.26 L/kg
Penicillin therapy	0.26 L/kg
Obesity (more than 30% of IBW)	$V = 0.26 [IBW + 0.4(TBT - IBW)]$
Cystic fibrosis	0.35
Acites/overhydration	$V = (0.26 \cdot DBW) + (TBW - DBW)$

4-The elimination rate constant of AG in the patient

$$k_e = 0.00293(\text{CrCl}) + 0.014 \text{ (h}^{-1}\text{)}$$

5- The suitable steady state concentration (peak & trough)

Sever infection (Pseudomonas aeruginosa, OR gram-negative pneumonia or septicemia)	8-10 µg/mL for tobramycin, gentamicin, and netilmicin. 25-30 µg/mL for Amikacin.
Moderate infections such as Intraabdominal infection	5-7 µg/mL for tobramycin, gentamicin, and netilmicin 15-25 for Amikacin.
Mild infection or with penecillin in endocarditis	3-5µg/mL for tobramycin, gentamicin, and netilmicin. 12-15 for Amikacin.

6-Dose model (intravenous bolus or intermittent infusion)

For intravenous bolus:

$$\tau = \frac{\ln C_{ss \text{ max}} - \ln C_{ss \text{ min}}}{K_{el}}$$

$$MD = C_{ss \text{ max}} * V_d (1 - e^{-K_{el} * \tau})$$

$$LD = C_{ss \text{ max}} * V_d$$

For intermittent infusion:

$$\tau = \frac{\ln C_{ss \max} - \ln C_{ss \min}}{K_{el}} + t'$$

$$MD = C_{ss \max} * k_{el} * V_d \left(\frac{1 - e^{-K_{el} * \tau}}{1 - e^{-K_{el} * t'}} \right)$$

$$LD = \frac{MD}{1 - e^{-K_{el} * \tau}}$$

Hartford Nomogram Method for Extended-Interval Dosing

1. Administer 7-mg/kg gentamicin with initial dosage interval

2- According to CL_{cr}, choose the INITIAL DOSAGE INTERVAL

ESTIMATED CrCl	INITIAL DOSAGE INTERVAL
≥60 mL/min	q24 h
40–59 mL/min	q36 h
20–39 mL/min	q48 h
<20 mL/min	monitor serial concentration and give next dose when <1 µg/mL

3- The aminoglycoside concentration should be measured 6–14 hours after dose (ideally first dose), and accordingly, the dose interval may be changed:

USE OF AMINOGLYCOSIDE SERUM CONCENTRATIONS TO CHANGE THE DOSE:

Linear Pharmacokinetics Method:

For this method to be valid, it should:

- 1-The measured concentration is a steady state
- 2-Make sure that the trough is within recommended range

$$D_{\text{new}} = (C_{ss,\text{new}}/C_{ss,\text{old}}) D_{\text{old}}$$

C_{ss} is the peak concentration.

Check the trough, it should be $<2 \mu\text{g/mL}$ for tobramycin, gentamicin or $<5-7 \mu\text{g/mL}$ for Amikacin.

$$C_{ss,\text{new}} = (D_{\text{new}}/D_{\text{old}}) C_{ss,\text{old}}$$

C_{ss} is the trough concentration.
