## Thermodynamics

BY
AQEEL A. KHUDHAIR

## Thermodynamics

- Thermodynamics is the study of the effects of work, heat, and energy on a system
- Thermodynamics is only concerned with macroscopic (large-scale) changes and observations.

- All of thermodynamics can be expressed in terms of four quantities
- Temperature (T)
- Internal Energy (U)
- Entropy (S)
- Heat (Q)

## Forms of energy

> The INTERNAL ENERGY, E of a system is the sum of the kinetic and potential energies of all the particles that compose the system or the total energy of a system.

## Definitions

- System: A region of the universe that we direct our attention to.
- Surroundings: Everything outside a system is called surroundings.

## You can't win (1st law of Thermodynamics)

- The first law of thermodynamics is an extension of the law of conservation of energy
- The change in internal energy of a system is equal to the heat added to the system minus the work done by the system

## The first law of thermodynamics

- $\Delta \mathrm{E}=\mathrm{Q}-\mathrm{W}$
- E is the enteral energy
- $Q$ is the heat
- W is work

## Process Terminology

- Adiabatic - no heat transferred
- Isothermal - constant temperature

## Adiabatic Process

- An adiabatic process transfers no heat
- therefore $Q=0$
- $\Delta E=Q-W$
- When a system expands adiabatically, W is positive (the system does work) so $\Delta \mathrm{E}$ is negative.
- When a system compresses adiabatically, W is negative (work is done on the system) so $\Delta \mathrm{E}$ is positive.

## Isothermal Process

- An isothermal process is a constant temperature process. Any heat flow into or out of the system must be slow enough to maintain thermal equilibrium
- For ideal gases, if $\Delta \mathrm{T}$ is zero, $\Delta \mathrm{E}=0$
- Therefore, $\mathrm{Q}=\mathrm{W}$
- Any energy entering the system (Q) must leave as work (W)

Maximum
work

By ideal gas equation
$\mathrm{PV}=\mathrm{nRT}$
$P=\frac{\mathrm{nRT}}{\mathrm{V}}$
Substitute in (i), we get.
$\mathrm{w}=-\int_{\nu_{1}}^{\nu_{2}} \frac{n R T}{V} \mathrm{~d} \mathrm{~V}$
$w=-n R T \int_{v_{1}}^{v_{2}} \frac{d v}{V}$
$w=-n R T\left[n V \int_{v_{1}}^{v_{2}}\left[\because \int \frac{d x}{x}=\ln \mathrm{n}\right]\right.$
$w=-n R T\left[\ln V_{2}-\ln V_{1}\right]$
$w=-n R T \ln \frac{V_{2}}{V_{1}}$
$w=-2.303 n R T \log \frac{V_{2}}{V_{1}} \quad[\ln x=2.303 \log x]$
$\operatorname{Since} \frac{P_{1} V_{1}}{}=P_{2} V_{2}$
$\frac{V_{2}}{V_{1}}=\frac{P_{1}}{P_{2}}$
$w=-2.303 n R T \log \frac{P_{1}}{P_{2}}$

Example 3-2. One mole of water in equilibrium with its vapor is converted into steam at $100^{\circ} \mathrm{C}$ and 1 atm . The heat absorbed in the process (i.e., the heat of vaporization of water at $100^{\circ} \mathrm{C}$ ) is about 9720 $\mathrm{cal} / \mathrm{mole}$. What are the values of the three first-law terms, $Q, W$, and $\Delta E$ ?
The amount of heat absorbed is the heat of vaporization, given as $9720 \mathrm{cal} /$ mole. Therefore,

$$
Q=9720 \mathrm{cal} / \mathrm{mole}
$$

The work $W$ performed against the constant atmospheric pressure is obtained by using equation (3-8), $W=P\left(V_{2}-V_{1}\right)$. Now $V_{1}$ is the volume of 1 mole of liquid water at $100^{\circ} \mathrm{C}$, or about 0.018 liter. The volume $V_{2}$ of 1 mole of steam at $100^{\circ} \mathrm{C}$ and 1 atm is given by the gas law, assuming that the vapor behaves ideally:

$$
V_{2}=\frac{R T}{P}=\frac{0.082 \times 373}{1}=30.6 \text { liters }
$$

It is now possible to obtain the work,
$W=P\left(V_{2}-V_{1}\right)=1 \times(30.6-0.018)=$
30.6 liters $\mathrm{atm} / \mathrm{mole}=741 \mathrm{ca} / \mathrm{mole}$

The internal energy change $\Delta E$ is obtained from the first-law expression

$$
\Delta E=Q-W=9720-741=8979 \mathrm{cal} / \mathrm{mole}
$$

## Example 3-4

What is the maximum work done in the isothermal reversible expansion of 1 mole of an ideal gas from 1 to 1.5 liters at $25^{\circ} \mathrm{C}$ ?
The conditions of this problem are similar to those of Example 3-2, except that equation (310) can now be used to obtain the (maximum) work involved in expanding reversibly this gas by 0.5 liters; thus,
$W=-(1$ mole)( 8.3143 joules/K mole)(298.15 K) In (1.5/1.0)
$W=-1005.3$ joules
P. 59

## Thermochemistry

- Thermochemical equation: a chemical equation that includes the enthalpy change
- Heat of reaction: the enthalpy change for a chemical equation exactly as it is written
- Heat of combustion: the heat of reaction for the complete burning of one mole of a substance

Exothermic process is any process that gives off heat - transfers therm from the system to the surroundings.

$$
\begin{aligned}
& 2 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\text { energy } \\
& \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \longrightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\text { energy }
\end{aligned}
$$

Endothermic process is any process in which heat has to be supplied to the system from the surroundings.

$$
\begin{aligned}
\text { energy }+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~s}) & \longrightarrow 2 \mathrm{H} 2(I)+\mathrm{O}_{2}(g) \\
\text { energy }+\mathrm{H}_{2} \mathrm{O}(s) & \longrightarrow \mathrm{H}_{2} \mathrm{O}(I)
\end{aligned}
$$

Enthalpy $(\mathrm{H})$ is used to quantify the heat flow into or out of a system i process that occurs at constant pressure.

$$
\Delta H=H \text { (products) }-H \text { (reactants) }
$$

$$
\Delta H=\text { heat given off or absorbed during a reaction }
$$

## Thermochemical Equations

## Heats of Combustion

The heat of combustion is the heat of reaction for the complete burning of one mole of a substance.

## Thermochemical Equations

## Heats of Combustion

Small amounts of natural gas within crude oil are burned off at oil refineries.
$\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \rightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{f})+890 \mathrm{~kJ}$

- This is an exothermic reaction.
- Burning 1 mole of methane releases 890 kJ of heat.
- The heat of combustion $(\Delta H)$ for this reaction is -890 kJ per mole of methane burned.

## Thermochemical Equations

## Heats of Reaction

Baking soda (sodium bicarbonate) decomposes when it is heated. This process is endothermic.
$2 \mathrm{NaHCO}_{3}(s)+85 \mathrm{~kJ} \rightarrow \mathrm{Na}_{2} \mathrm{CO}_{3}(s)+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{CO}_{2}(\mathrm{~g})$

The carbon dioxide released in the reaction causes muffins to rise while baking.

## Thermochemical Equations

-Heats of Reaction

$$
2 \mathrm{NaHCO}_{3}(s)+85 \mathrm{~kJ} \rightarrow \mathrm{Na}_{2} \mathrm{CO}_{3}(s)+\mathrm{H}_{2} \mathrm{O}(J)+\mathrm{CO}_{2}(g)
$$

Remember that $\Delta H$ is positive for endothermic reactions.
Therefore, you can write the reaction as follows:
$2 \mathrm{NaHCO}_{3}(s) \rightarrow \mathrm{Na}_{2} \mathrm{CO}_{3}(s)+\mathrm{H}_{2} \mathrm{O}()+\mathrm{CO}_{2}(g)$ $\Delta H=85 \mathrm{~kJ}$

## Thermochemical Equations

## Heats of Reaction

The amount of heat released or absorbed during a reaction depends on the number of moles of the reactant involved.

- The decomposition of 2 moles of sodium bicarbonate requires 85 kJ of heat.
- Therefore, the decomposition of 4 moles of the same substance would require twice as much heat, or 170 kJ .

## Thermochemical Equations

- Heats of Reaction

To see why the physical state of the reactants and products must be stated, compare the following two equations.

$$
\begin{array}{ll}
\mathrm{H}_{2} \mathrm{O}(\Lambda) \rightarrow \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g)_{2} & \Delta H=285.8 \mathrm{~kJ} \\
\mathrm{H}_{2} \mathrm{O}(g) \rightarrow \mathrm{H}_{2}(g)+\mathrm{O}_{2}\left(g g_{2}^{*}\right. & \frac{\Delta H=241.8 \mathrm{~kJ}}{\text { difference }=44.0 \mathrm{~kJ}}
\end{array}
$$

## You can'ł break even (2 ${ }^{\text {nd }}$ Law of Thermodynmics)

- Second law of thermodynamics is about spontaneity of processes.
- Heat does not go from a colder body to a hotter body.
- The $2^{\text {nd }}$ Law can also be stated that heat flows spontaneously from a hot object to a cold object (spontaneously means without the assistance of external work)

The Second Law of Thermodynamics says that processes that involve the transfer or conversion of heat energy are irreversible

There exists a useful thermodynamic variable called entropy (S). A natural process that starts in one equilibrium state and ends in another will go in the direction that causes the entropy of the system plus the environment to increase for an irreversible process and to remain constant for a reversible process.

$$
\mathrm{S}_{\mathrm{f}}=\mathrm{S}_{\mathrm{i}} \text { (reversible) } \quad \mathrm{S}_{\mathrm{f}}>\mathrm{S}_{\mathrm{i}} \text { (irreversible) }
$$

## Concerning the $2^{\text {nd }}$ Law

- The second law of thermodynamics introduces the notion of entropy (S), a measure of system disorder (messiness)
- $U$ is the quantity of a system's energy, $S$ is the quality of a system's energy.

## Implications of the $2^{\text {nd }}$ Law

- Time marches on
- If you watch a movie, how do you know that you are seeing events in the order they occurred?
- If I drop a raw egg on the floor, it becomes extremely "disordered" (greater Entropy) - playing the movie in reverse would show pieces coming together to form a whole egg (decreasing Entropy) - highly unlikely!

## Direction of a Process

- The $2^{\text {nd }}$ Law helps determine the preferred direction of a process
- A reversible process is one which can change state and then return to the original state
- This is an idealized condition - all real processes are irreversible

## Example 3-8

What is the entropy change accompanying the vaporization of 1 mole of water in equilibrium with its vapor at $25^{\circ} \mathrm{C}$ ? In this reversible isothermal process, the heat of vaporization $\Delta H_{\mathrm{v}}$ required to convert the liquid to the vapor state is $10,500 \mathrm{cal} / \mathrm{mole}$.
The process is carried out at a constant pressure, so that $Q_{P}=\Delta H_{v}$, and because it is a reversible process, the entropy change can be written as

$$
\Delta S=\frac{\Delta H_{\mathrm{v}}}{T}=\frac{10,500}{298}=35.2 \mathrm{cal} / \mathrm{mole} \mathrm{deg}
$$

- In case of irreversible processes, change in entropy can be carried out as below:

$$
\Delta S=C_{P} \ln \frac{T_{2}}{T_{1}}=2.303 C_{P} \log \frac{T_{2}}{T_{1}}
$$

## Free energy

## - $\Delta \mathrm{G}=\Delta \mathrm{H}-\mathrm{T} \Delta \mathrm{S}$

- $\Delta H$ refers to the heat change for a reaction. A positive $\Delta H$ means that heat is taken from the environment (endothermic). A negative $\Delta \mathrm{H}$ means that heat is emitted or given to the environment (exothermic).
- $\Delta \mathrm{G}$ is a measure for the change of a system's free energy.
- If $\Delta G<0$, the process occurs spontaneously.
- If $\Delta G=0$, the system is at equilibrium.
- If $\Delta G>0$, the process is not spontaneous as written but occurs spontaneously in the reverse direction.

## $\Delta \mathrm{G}=\Delta \mathrm{H}-\mathrm{T} \Delta \mathrm{S}$

| Case | $\Delta \mathrm{H}$ | $\Delta \mathrm{S}$ | $\Delta \mathrm{G}$ | Reaction |
| :--- | :---: | :---: | :---: | :--- |
| 1. high temperature | - | + | - | Spontaneous |
| 2. low temperature | - | + | - | Spontaneous |
| 3. high temperature | - | - | + | Nonspontaneous |
| 4. low temperature | - | - | - | Spontaneous |
| 5. high temperature | + | + | - | Spontaneous |
| 6. low temperature | + | + | + | Nonspontaneous |
| 7. high temperature | + | - | + | Nonspontaneous |
| 8. low temperature | + | - | + | Nonspontaneous |

## Example 3-10

$\Delta H$ and $\Delta S$ for the transition from liquid water to ice at $-10^{\circ} \mathrm{C}$ and at 1 atm pressure are -1343 $\mathrm{cal} / \mathrm{mole}$ and $-4.91 \mathrm{cal} / \mathrm{mole}$ deg, respectively. Compute $\Delta G$ for the phase change at this temperature $\left(-10^{\circ} \mathrm{C}=263.2 \mathrm{~K}\right)$ and indicate whether the process is spontaneous. Write $\Delta G=-1343-[263.2 \times(-4.91)]=-51 \mathrm{cal} / \mathrm{mole}$ $=-213$ ioules

The process is spontaneous, as reflected in the negative value of $\Delta G$.

## You can'† get out (3rd Law)

- No system can reach absolute zero
- This is one reason we use the Kelvin temperature scale. Not only is the internal energy proportional to temperature, but you never have to worry about dividing by zero in an equation!
- There is no formula associated with the $3^{\text {rd }}$ Law of Thermodynamics
- https://www.youtube.com/watch?v=kuGmsnzibpE

## $3^{\text {rd }}$ Law of Thermodynamics

Absolute zero can't be reached - who would want to!

How Stuff Works: 10 Scientific Laws \& Theories You Really Should Know

## 3rd Law of Thermodynamics

- It says that however it is impossible to reach absolute zero, but at which ( 0 Kelvin), there will be no entropy $(\mathrm{S})$ and a pure crystalline structure of matter will form.
