# Experiment No. (1) 

## lmage Types

## Aim:

The four image kinds are demonstrated and a conversion from one image type to others is applied using a suitable conversion formula(s).

Theory:
Image could be classified into four categories,

1. True colour or Red Green Blue (RGB) image. This kind of image consists of three colored planes, each one represent a 2D matrix. The data class for this kind of image might be unsigned integer ( 0 $255)$, double, or scaled double ( $0-1$ ), e.g; the jpg or png image
2. Indexed image. It consists of one main matrix with a color map associated for each pixel value. The data class might be a scaled double value, e.g; tif image
3. Gray-scale or intensity image which consist of one matrix. The data class for this image type might be uint $(0-255)$ or scaled double $(0-1)$. These values represents the intensity of gray level values
4. Binary image, consists of one matrix with $0 / 1$ data-class value

- The RGB to Gray-scale Conversion

There are four algorithms for converting color to gray-scale. If each color pixel is described by a triple ( $\mathrm{r}, \mathrm{g}, \mathrm{b}$ ) of intensities for red, green, and blue. These formulas could be applied separately to map the colored pixel to its equivalent gray level value::

1. The lightness method which averages the most prominent and least prominent colors: $(\max (\mathbf{R}, \mathbf{G}, \mathbf{B})+\boldsymbol{\operatorname { m i n }}(\mathbf{R}, \mathbf{G}, \mathbf{B})) / 2$.
2. The average method, simply averages the values: $(\mathbf{R}+\mathbf{G}+\mathbf{B}) / \mathbf{3}$.
3. The luminosity method is a more sophisticated version of the average method. It also averages the values, but it forms a weighted average to account for human perception. We're more sensitive to green than other colors, so green is weighted most heavily. The formula for luminosity is: $0.21 \mathrm{R}+\mathbf{0 . 7 1 G}+\mathbf{0 . 0 7} \mathrm{B}$.
4. The weighted average method is given by the formula.

$$
\text { Gray }=0.299 R+0.587 G+0.114 B
$$

Example: A shade of dark purple has an $(\mathrm{r}, \mathrm{g}, \mathrm{b})$ value of $(100,0,150)$. The weighted average is: gray $=0.299(100)+0.587(0)+0.114(150)$,

## Converting lmage Types

Matlab also contains many built-in functions for converting different image types. See table below;

| Function | Use | Format |
| :--- | :--- | :--- |
| Ind2gray | Indexed to grayscale | $\mathrm{y}=\mathrm{ind} 2$ gray(x,map); |
| Gray2ind | Grayscale to indexed | [y,map]=gray2ind(x); |
| Rgb2gray | RGB to grayscale | $\mathrm{y}=\mathrm{rgb2gray}(\mathrm{x}) ;$ |
| Rgb2ind | RGB to indexed | [y,map]=rgb2ind; |
| Ind2rgb | Indexed to RGB | $\mathrm{y}=$ ind2rgb(x,map); |
| Mat2gray | Matrix to grayscale | $\mathrm{Y}=$ mat2gray(x); |

Example : The green and red color plane of image rgbimage.jpg are swapped
$\mathrm{f}=$ imread('rgbimage.jpg');
red $=f(:,:, 1)$;
$\mathrm{g}(:, \cdot, 1)=\mathrm{f}(:,, ; 2)$;
g(:.;,2) = red;
$\mathrm{g}(:, \cdot, 3)=\mathrm{f}(\cdot,, ; 3)$;
imshow(g);

## Requirements:

1. Read and display your stored images " 1 rgb.jpg" and " 1 ind.tif"
2. Find the equivalent gray (intensity) image for " 1 rgb.jpg" and " 1 ind.tif" using the built-in MATLAB functions
3. Repeat step 2 using for-Loop statement and four conversion formulas. Which formula is better (use subplot ( $\mathrm{m}, \mathrm{n}, \mathrm{p}$ ) function for displaying)
4. Can you re-convert a gray value back to its equivalent RGB color code?
5. Fill the following table:

| image | $\begin{gathered} \hline \text { Size } \\ (\text { row } \times \text { col. } \times \mathrm{dim}) \\ \hline \end{gathered}$ | Plane Size |  |  | $\begin{gathered} \hline \text { Gray-level size } \\ (\text { row } \times \text { col. } \times \mathrm{dim}) \\ \hline \end{gathered}$ | $\begin{gathered} \hline \text { Binary size } \\ (\text { row } \times \text { col } . \times \mathrm{dim} \text { ) } \\ \hline \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Red | Green | Blue |  |  |
| 1rgb.jpj |  |  |  |  |  |  |
| 1ind.tif |  |  |  |  |  |  |

6. Write a program to display the individual red, green, and blue channels of "1rgb.jpg" colour image. Use subplot( ) function for displaying
