

Method for setting out the curve

(1)

- 1) By tape and offset.
- 2) By angle and distance measurement.
- 3) By angle measurement only.

- 1) By tape and offset
- A. offsets from the long chord
 - B. offsets from the tangent
 - C. offsets from chord produced (by deflection distance).
 - D. offsets from radius.

A. offsets from the long chord.

The major offset is y in Figure drawn below:

To find Equation for major offset by using the set equation below:

$$y = R - k \quad \dots \dots (1)$$

From triangle OPC

$$R^2 = k^2 + x^2 \Rightarrow k = \sqrt{R^2 - x^2} \quad \dots (2)$$

Sub. Equation (2) into (1) the major offset y is:

$$y = R - \sqrt{R^2 - x^2} \quad \dots \dots (3)$$

To find another offset as follows:

$$y_n = AB - k \quad \dots \dots (4)$$

From triangle ABO

$$R^2 = AB^2 + x^{*2} \Rightarrow AB = \sqrt{R^2 - x^{*2}} \quad \dots (5)$$

Sub. Equation (5) into (4):

$$y_n = \sqrt{R^2 - x^{*2}} - k \quad \dots \dots (6)$$

Example) A road as simple circular curve with radius 40m and long chord 60m. Calculate the offsets distance from the chord at 10m intervals. (2)

Sol.

$$\text{major offset } (y) = R - \sqrt{R^2 - x^2}$$

$$= 40 - \sqrt{40^2 - 30^2} = 13.542 \text{ m}$$

$$k = R - y = 40 - 13.542 = 26.46 \text{ m}$$

offset y_1 ($x = 20$ from ϕ of curve)

$$y_1 = \sqrt{R^2 - x^2} - k$$

$$= \sqrt{40^2 - 20^2} - 26.46 = 8.18 \text{ m}$$

offset y_2 ($x = 10$ from ϕ of curve)

$$y_2 = \sqrt{R^2 - x^2} - k$$

$$= \sqrt{40^2 - 10^2} - 26.46 = 12.27 \text{ m}$$
