

**Ex.** A simple refrigeration cycle operates between  $-10\text{ }^{\circ}\text{C}$  and  $40\text{ }^{\circ}\text{C}$  in evaporator and condenser respectively. If R-134a flows in the system at a rate of  $0.025\text{ kg/s}$ . Find the COP of the cycle in three modes of operation:

- Ideal operation.
- Real operation taking the compressor isentropic efficiency to be 88%.
- Same as in (b) with a pressure drop in condenser to be 5% of its inlet pressure.

**sol.**

**a) Ideal mode**

at  $T_1 = 10\text{ }^{\circ}\text{C}$  from sat. tables of R-134a  $h_1 = 392.9\text{ kJ/kg}$ ,  $s_1 = 1.7341\text{ kJ/(kg }^{\circ}\text{C)} = s_{2s}$

at  $T_{2, \text{sat}} = 40\text{ }^{\circ}\text{C}$  from sat tables  $P_2 = 1017\text{ kPa}$

from superheated tables at  $1000\text{ kPa}$  and  $s_{2s} = 1.7341\text{ kJ/(kg }^{\circ}\text{C)}$ ,  $h_2 = 425.7\text{ kJ/kg}$

at  $T_3 = 40\text{ }^{\circ}\text{C}$  from sat tables,  $h_3 = h_4 = 256.6\text{ kJ/kg}$

$$\text{COP} = (h_4 - h_1) / (h_{2s} - h_1) = (256.6 - 392.9) / (425.7 - 392.9) \quad \text{COP} = 4.15 \text{ (Ideal operation)}$$

**b) Real operation (compressor irreversibility only)**

$$\eta_c = (h_{2s} - h_1) / (h_2 - h_1) \quad 0.88 = (425.7 - 392.9) / (h_2 - 392.9) \quad h_2 = 430.1\text{ kJ/kg}$$

$$\text{COP} = (h_4 - h_1) / (h_2 - h_1) = (256.6 - 392.9) / (430.1 - 392.9) \quad \text{COP} = 3.56 \text{ (Real operation)}$$

**c) Real operation ((compressor irreversibility and pressure drop in condenser)**

the new pressure in condenser is found as follows:

$$P_3 = P_2 - 0.05 \times P_2 = P_2 \times 0.95 = 1000 \times 0.95 = 950\text{ kPa}$$

at  $950\text{ kPa}$  from sat tables,  $h_3 = h_4 = 253.6\text{ kJ/kg}$

$$\text{COP} = (h_4 - h_1) / (h_2 - h_1) = (253.6 - 392.9) / (430.1 - 392.9) \quad \text{COP} = 3.64 \text{ (Real operation)}$$
