## Measures of Dispersion and Variability

## Variance :

Variance in statistics is a measurement of the spread between numbers in a data set. That is, it measures how far each number in the set is from the mean and therefore from every other number in the set, so Variance defined as the average of the squared differences from the mean. Variance measures how far a data set is spread out.

$$
V=\frac{\sum_{i=1}^{n}(X i-\bar{X})^{2}}{N}
$$

Where:
$\mathrm{V}=$ Variance
xi = Value of each data point
$\overline{\mathrm{x}}=$ Mean
$\mathrm{N}=$ Number of data points

Variance can be negative. A zero value means that all of the values within a data set are identical.

If the variance is low that's mean the data collect near average, while If the variance is high the data will spread from the average.

## Problem 1:

The heights (in cm) of students of a class is given to be 163, 158, 167, 174, 148. Find the variance.

Solution:
To find the variance, we need to find the mean of the given data and total members in the data set.

Total number of elements, $\mathrm{N}=5$

$$
\bar{X}=\frac{163+158+167+174+148}{5}=162
$$

The formula for variance is,

$$
\mathrm{V}=\frac{\sum_{i=1}^{n}(X i-\bar{X})^{2}}{N}
$$

Now putting the values in the formula we get,

$$
\begin{gathered}
V=\frac{(162-163)^{2}+(158-163)^{2}+(167-163)^{2}+(174-163)^{2}+(148-163)^{2}}{5} \\
V=\frac{(-1)^{2}+(-5)^{2}+(4)^{2}+(11)^{2}+(-15)^{2}}{5}=77.6
\end{gathered}
$$

Hence, the variance is found to be 77.6
variance for grouped data

$$
\begin{aligned}
\text { variance }= & \frac{\sum_{i=1}^{n} f i(X i-\bar{X})^{2}}{\sum_{i=1}^{n} f i} \\
\bar{x} & =\frac{\sum f x}{n}
\end{aligned}
$$

Find the variance of the following data:

| Classes | Frequency(f) |
| :---: | :---: |
| $30-34$ | 4 |
| $35-39$ | 5 |
| $40-44$ | 2 |
| $45-49$ | 9 |
| TOTAL | $\mathbf{2 0}$ |

Solution:

| Classes | Frequency(f) | Mid classes (x) | f.x | x-mean | (x-mean) $^{2}$ | f.(x-mean) ${ }^{2}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :--- |
| $30-34$ | 4 | 32 | 128 | $32-41=-9$ | 81 | $4 * 81=324$ |
| $35-39$ | 5 | 37 | 185 | $37-41=-4$ | 16 | $5^{*} 16=80$ |
| $40-44$ | 2 | 42 | 84 | $42-41=1$ | 1 | $2^{*} 1=2$ |
| $45-49$ | 9 | 47 | 423 | $47-41=6$ | 36 | $9 * 36=324$ |
| TOTAL | $\mathbf{2 0}$ |  |  |  |  | $\mathbf{7 3 0}$ |

Mean $\bar{x}=\frac{\sum \mathbf{f} * \mathbf{x}}{n}=\frac{820}{20}=41$

$$
\text { variance }=\frac{\sum_{i=1}^{n} f i(X i-\bar{X})^{2}}{\sum_{i=1}^{n} f i}=\frac{730}{20}=36.5
$$

## Coefficient of variation (CV):

The coefficient of variation (CV) is a statistical measure of the dispersion of data points in a data series around the mean. The coefficient of variation represents the ratio of the standard deviation to the mean, and it is a useful statistic for comparing the degree of variation from one data series to another, even if the means are drastically different from one another.

The coefficient of variation is helpful when using the risk/reward ratio to select investments. For example, in finance, the coefficient of variation allows investors to determine how much volatility, or risk, is assumed in comparison to the amount of return expected from investments.

Ideally, the coefficient of variation formula should result in a lower ratio of the standard deviation to mean return, meaning the better risk-return trade-off. Note that if the expected return in the denominator is negative or zero, the coefficient of variation could be misleading.

$$
\text { Coefficient of variation }(\mathrm{CV})=\frac{\text { standard deviation }}{\text { Mean }}
$$

Example: Find CV of $\{13,35,56,35,77\}$
Solution:
Number of terms (N) = 5
Mean:

$$
\text { Mean }=\frac{13+35+56+35+77}{5}=43.2
$$

Standard Deviation (SD):
Formula to find SD is

$$
S . D=\sqrt{\frac{\sum_{i=1}^{n}(X i-\bar{X})^{2}}{n}}
$$

$S . D=\sqrt{\frac{(13-43.2)^{2}+(35-43.2)^{2}+(56-43.2)^{2}+(35-43.2)^{2}+(77-43.2)^{2}}{5}}$
$S . D=24.25$

Coefficient of vari

CV = Standard Deviation / Mean
= 24.2528/43.2
$=0.5614$

## Standard Error:

The standard error is a statistical term that measures the accuracy with which a sample distribution represents a population by using standard deviation. In statistics, a sample mean deviates from the actual mean of a population-this deviation is the standard error of the mean.

It is used to measure the amount of accuracy by which the given sample represents its population.

When you take measurements of some quantity in a population, it is good to know
how well your measurements will approximate the entire population.
A large standard error would mean that there is a lot of variability in the population, so different samples would give you different mean values.

A small standard error would mean that the population is more uniform, so your sample mean is likely to be close to the population mean.

$$
\text { Standard Error }(\mathrm{SE})=\frac{\text { Standard Deviation }}{\sqrt{N}}
$$

Where: N is the number of observation.

## Example

## Calculate the standard error of the given data:

(5, 10, 12, 15, 20)
Solution: First we have to find the mean of the given data;
Mean $=(5+10+12+15+20) / 5=62 / 5=10.5$
Now, the standard deviation can be calculated as;

$$
S=\sqrt{\frac{(5-10.5)^{2}+(10-10.5)^{2}+(12-10.5)^{2}+(15-10.5)^{2}+(20-10.5)^{2}}{5}}
$$

After solving the above equation, we get;
S $=5.35$
Therefore, SE can be estimated with the formula;

$$
\begin{gathered}
\text { Standard Error }(\mathrm{SE})=\frac{\text { Standard Deviation }}{\sqrt{N}} \\
\text { SE }=\frac{5.35}{\sqrt{5}}=2.39
\end{gathered}
$$

Advantages and disadvantages of measures of dispersion

| Measures of Variability | Advantages | Disadvantages |
| :---: | :---: | :---: |
| Range | It is easier to compute | The value of range is affected by only two extreme scores |
|  | It can be used as a measure of variability where precision is not required | It is not very stable from sample to sample |
|  |  | It is not sensitive to total condition of the distribution |
|  |  | It is dependent on sample size, being greater when sample size is greater |
| Inter quartile Range | It is less sensitive to the presence of a few very extreme scores than is standard deviation | The sampling stability of IQR is good but it is not up to that of standard deviation |
|  | If the distribution is skewed, IQR is a good measure of variation. |  |
| Standard Deviation | It is resistant to sampling variation It is of high use both in descriptive and inferential statistics | It is responsive to exact position of each score in the distribution |
|  |  | It is more sensitive than IQR to the presence of few extreme scores in the distribution |
| Variance | provide a summary of individual observations around the mean | sensitive to outliers |
| Coefficient of variation | used to compare two or more distribution that have different means | Does not vary with the magnitude of the mean |
