# Chapter Eight
## Weather Radar

Radar Principles

- The components of a radar system are:

    ✓ **Transmitter:** The transmitter generates pulses of radio frequency (RF) radiation.

    ✓ **Receiver:** The receiver detects the returned energy.

    ✓ **Antenna:** The antenna focuses the outgoing beam and the incoming radiation.

    ✓ **Radar Display Systems:**

        ▪ **Plan Position Indicator (PPI):** maps the received signals on polar coordinates in plain view.

        ▪ **Range Height Indicator (RHI):** shows the vertical structure of echoes which is generated when the antenna scans in elevation with azimuth fixed.

        ▪ Microprocessors are used to convert the signals to reflectivity Z or rainfall rate.
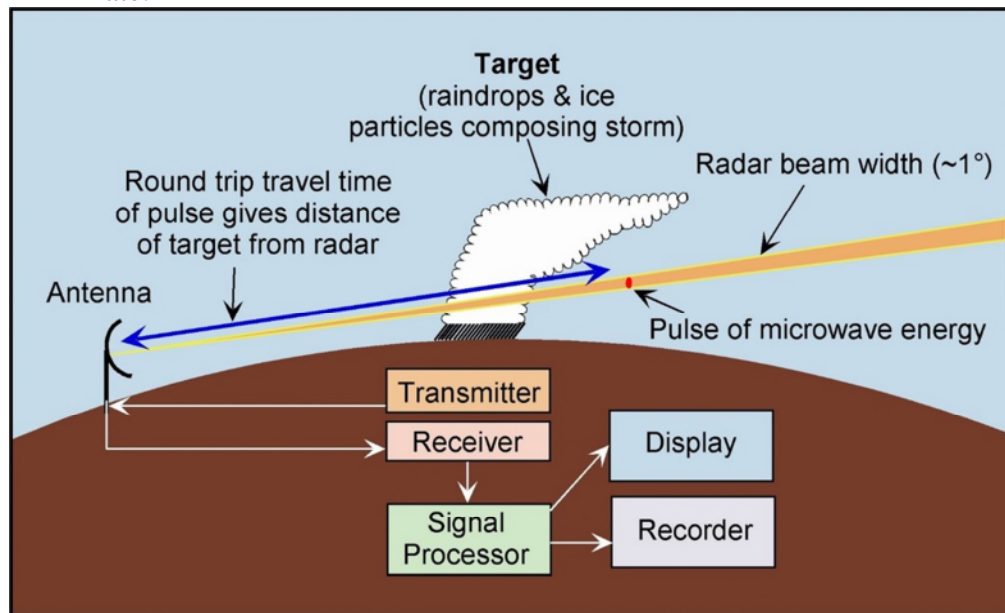

PPI (plan-position indicator):

Reflectivity Z_{hh} (dBZ)
RHI (range-height indicator):

Reflectivity Z_{hh} (dBZ)
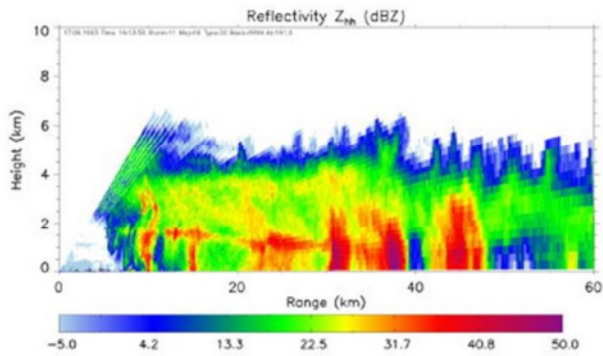

- The radar measures the distance to the target by measuring the time between the transmission of a pulse and the detection of the return pulse.

- The total distance traveled by the pulse is $2r$, where **r** is the distance to the target.

- The time of travel is the total distance divided by the speed of the radiation, c,

$$t = 2r / c \qquad (8.1)$$

Therefore, if the travel time is known the distance to the target can be deduced by

$$r = ct / 2 \qquad (8.2)$$

Radar Parameters

❖ **Pulse Width:** Denoted as τ, the pulse width is the transmission duration of the pulse (usually measured in microseconds). Also called pulse duration.

- The pulse width determines the range resolution of the radar. If two targets are separated by distance Δr that is less than $c\tau$, they will appear as a single target.

- The pulse width also determines the minimum range of the radar. Since the radar cannot detect incoming pulses while it is transmitting, the minimum range of a radar is

$$r_{min} = c\tau/2 \tag{8.3}$$

❖ **Pulse Repetition Frequency:** Abbreviated as PRF, and denoted as f_r, this is the number of pulses per second transmitted by the radar.

- The maximum unambiguous range of a radar is

$$r_{max} = \frac{c}{2f_r} \tag{8.4}$$

❖ **Peak Power:** The maximum power of the pulse, denoted as P_t. Usually measured in Watts.

❖ **Wavelength:** Denoted by λ, this is the wavelength of the radiofrequency wave transmitted by the radar. For weather radars this is in the microwave part of the spectrum. Wavelengths of 3-10 cm are commonly used.

❖ **Beamwidth:** Denoted as θ, this is the angular width of the radar beam.

❖ **Antenna Area:** Denoted as A_e, this is the area of the aperture of the antenna.

- For a given beamwidth, as the wavelength increases a larger antenna area is required. Thus, a radar operating at a wavelength of 10 cm will have a larger antenna than one operating at 3 cm.

❖ **Antenna Gain:** The gain, G, describes the focusing of the radar beam.
- If the antenna transmitted isotropically (evenly in all directions of a sphere) the power incident on a small target of cross-section A_t at a distance r would be

$$P_{iso} = P_t \frac{\omega}{4\pi} \tag{8.5}$$

where ω is the solid angle of the target with respect to the radar.

- If the target is small, such that we can use the small-angle approximation, then the solid angle of the target is $\omega = A_t / r^2$ and the power incident on the target from (8.5) is

$$P_{iso} = \frac{P_t A_t}{4\pi r^2} \qquad (8.6)$$

- The gain is the power intercepted by the target divided by what the power would be if the antenna transmitted isotropically,
$$G = P_\sigma / P_{iso} \qquad (8.7)$$

- Therefore, the power intercepted by a target is

$$P_\sigma = G \frac{P_t A_t}{4\pi r^2} \qquad (8.8)$$

- The gain is a dimensionless number that is greater than one.

- Gain is related to the wavelength of the radar, and the antenna aperture, by

$$G = \frac{4\pi A_e}{\lambda^2} \qquad (8.9)$$

The Radar Equation for a Single Target

- A target of cross-sectional area A_t at a distance r from the radar intercepts an amount of power given by (8.8), repeated here,

$$P_\sigma = G \frac{P_t A_t}{4\pi r^2}$$

- If the target reflects (or reradiates) this same amount of energy isotropically, the amount of power received by the radar would be

$$P_r = P_\sigma \frac{\omega_e}{4\pi} \tag{8.10}$$

  where ω_e is the solid angle of the antenna with respect to the target.

- ω_e is given by

$$\omega_e = \frac{A_e}{r^2} \tag{8.11}$$

  and using (8.11) and (8.8) in (8.10) results

$$P_r = P_t \frac{G A_t A_e}{16\pi^2 r^4} \tag{8.12}$$

- From (8.9) we know

$$A_e = \frac{G \lambda^2}{4\pi}$$

  and substituting this into (8.12) results in the radar equation for an isotropically reflecting target of cross-sectional area A_t

$$P_r = P_t \frac{G^2 \lambda^2}{64\pi^3 r^4} A_t \tag{8.13}$$

- The cross-sectional area A_t in (8.13) is usually replaced with the *backscattering cross section*, which is also called the *effective cross section*, or *radar cross section*, σ.
    - ➤ The effective cross section is the cross section that the target appears to have, and may either be larger or smaller than the actual physical cross section of the target.

    - ➤ A target that is very absorptive will reflect and return a small amount of the radar power that hits the target. Thus, the target will appear to be much smaller to the radar, and therefore have a smaller radar cross section. This is the basis of stealth technology to hide aircraft and ships from radar detection.

> ➤ The effective cross section takes into account the shape and composition of the target.

- In terms of effective cross section, the radar equation becomes

$$P_r = P_t \frac{G^2 \lambda^2}{64\pi^3 r^4} \sigma \tag{8.14}$$

Radar Equation for Hydrometeors

- Rain drops are much, much smaller than the wavelength of the radar radiation, and therefore scatter like Rayleigh scatters where Rayleigh scatters applies to particles that are small compared to the wavelength (λ) of the radar (remember why the sky is blue?).

- Rayleigh scattering theory gives the backscattering cross section of a spherical droplet of diameter D as

$$\sigma = \frac{\pi^5}{\lambda^4} |K|^2 D^6 \tag{8.15}$$

where K is the complex index of refraction of sphere $K = (m^2-1)/(m^2+2)$ and $m = n-ik$ with n is refractive index and k is absorption coefficient.

- Substituting (8.15) into (8.14) gives

$$P_r = P_t \frac{G^2}{64 r^4} \frac{\pi^2}{\lambda^2} |K|^2 D^6 \tag{8.16}$$

- If the radar signal scatters off of multiple droplets within the volume of the radar pulse, the returned power is the sum of the powers from all the droplets,

$$\bar{P}_r = P_t \frac{G^2}{64 r^4} \frac{\pi^2}{\lambda^2} |K|^2 \sum D^6 \tag{8.17}$$

- We have included an overbar over the P_r to indicate we are really dealing with an average return power.

- Radar *reflectivity* is defined as

$$Z = \frac{\sum D^6}{V} \tag{8.18}$$

where V is the volume sampled by the radar pulse.

- Reflectivity has MKS units of m^3, but is usually reported in units of $mm^6 \, m^{-3}$.

- Reflectivity is essentially backscattering cross section per volume.

- The geometric volume sampled by the radar beam is

$$V = \pi \left(\frac{r\theta}{2} \right)^2 \frac{c\tau}{2} \tag{8.19}$$

However, the radar beam is not really uniform over this volume, and the volume doesn't really have 'sharp' edges or boundaries. The radar energy is strongest in the center of the volume, and tapers off toward the edges. Therefore, it is more appropriate to use an *effective radar volume* given by

$$V_{eff} = \frac{\pi}{2\ln 2} \left(\frac{r\theta}{2} \right)^2 \frac{c\tau}{2} \tag{8.20}$$

- Using (8.20) in (8.18), and then rearranging, gives us

$$\sum D^6 = \frac{\pi}{16\ln 2} (r\theta)^2 c\tau Z \tag{8.21}$$

and using (8.21) in (8.17) result in the *radar equation for hydrometeors*,

$$\bar{P}_r = \frac{\pi^3 c}{1024\ln 2} \left(\frac{P_t \tau G^2 \theta^2}{\lambda^2} \right) \left(|K|^2 \frac{Z}{r^2} \right) \tag{8.22}$$

$$\text{Term A} \qquad \text{Term B}$$

- Term A consists of properties of the radar.

- Term B consists of properties of the target.
