## Experiment No. 6

## Experiment Name: Intensity of the air fronts

The aim of the experiment: Estimating geostrophic winds from synoptic maps and calculating the slopes of air fronts.

Theory: Suppose that warm air climbs over cold air, resulting a transition zone between them called an air front. The transition zone is characterized by a sudden change in temperature, while the atmospheric pressure values on both sides of the front do not change. Therefore, from the values of the geostrophic winds Vg 1 and Vg 2 and the temperatures T 1 and T 2 on both sides of the front, the slope of the front can be included from following relationship:
$\boldsymbol{\operatorname { t a n }} \boldsymbol{\theta}=-\boldsymbol{\partial z} / \boldsymbol{\partial} \mathrm{x}=-(\mathbf{f} \mathbf{~ T} / \mathrm{g})(\mathbf{V g 2 - V g} 1 / \mathrm{T} 1-\mathrm{T} 2)$
Where:
$\mathrm{f}=1 \mathbf{1 0}^{-4} / \mathbf{s e c}$
$\overline{\mathrm{T}}$ : average temperature in absolute scale on both sides of the front $=(\mathbf{T 1 + T 2 )} / \mathbf{2}$
Vg: Geostrophic wind components can be estimated from the analyzed map according to the following equation:
$\mathbf{V g}=(9.8 \Delta z / 2 \Omega \sin$ Ø $)(K / \Delta h)$
$\Omega=7.29 \times 10^{-5} / \mathrm{sec}$

## Where:

$K=1$ : the deformation factor resulting from the projection of the map, so that its value is one at latitudes $\underline{30^{\circ}}$ and $\underline{60^{\circ}}$ and increases at the poles,

Ø=latitude
$\Delta \mathbf{Z}$ : the interval of contour lines of the analyzed map,
$\Delta \mathrm{h}$ : the distance between the contour lines in centimeters.
The value between the brackets can be a fixed value. along a specific latitude and a specific map.

Fronts are steep and strong at $1 / 50$ mile, while low at $1 / 300$ mile.

Tools: surface pressure map of 850 mb .

## Methodology:

1. Point the variables of the left side of the forehead with the number 1 and the variables of the right side with the number 2.
2. Starting from latitude $30^{\circ}$ and along it, using the usual ruler, measure the distance between the first two consecutive contour lines on the left side $(1 \Delta \mathrm{~h})$ and determine the average temperature between these two lines from the information on the station or from the isothermal lines.
3. Using Equation (2), calculate Vg1 and write the results in Table (1) below.
4. Repeat steps 3 and $\mathbf{4}$ for two more consecutive lines along the previous line of latitude and calculate $1 \Delta \mathrm{~h}$ again.
5. Repeat Operation Steps 3,4 , and 5 for the right side.
6. Repeat steps $3,4,5$, and 6 for latitudes $35^{\circ}$ and $40^{\circ}$.
7. Complete the required calculations in the columns labeled $\mathrm{Vg} 1-\mathrm{Vg} 2$ and T1-T2.
8. Calculate the slope of the front for each line of latitude and for each two successive lines on either side of the front.
9. Calculate the average slope of the front at all latitudes.

## Table (1): variables of equation (2) for Calculations the front slope.

|  | $\begin{aligned} & \text { Vg2- } \\ & \operatorname{Vg1(m/s)} \end{aligned}$ | T1- <br> T2(k) | Right side(2) |  |  | (1) Left side |  |  | (f) $\mathbf{S}^{-1}$ | (0) ${ }^{\circ}$ |

|  |  |  |  |  |  |  |  |  |  |  |

## Discussion:

O1: Predict the intensity of the front at every $\emptyset$ ?
Q2: Does the slope of the front have a relationship with the weather? What is the weather condition based on your results in this experiment?
O3: Draw the $\mathrm{Vg} 2-\mathrm{Vg} 1$ points on the y -axis and the values of $\mathrm{T} 1-\mathrm{T} 2$ on the x -axis. Also calculate the rate of slope of the front and compare it with the result in Step No. 9?
Q4: Draw the relationship between $\varnothing$ and $\Theta$ and what do you conclude from it?
