## Lab No. (2)

## Calculate the frictional velocity $u_{*}$

Aims: To calculate the frictional velocity $u_{*}$ and the length of the surface roughness $Z_{0}$ from the graph.

## Tools:

1- Air tunnel.
2- Hot-wire anemometer.
4- Obstacles.

## Theoretical part :

Shear stress $\tau$ can be defined using the Frictional velocity $u_{*}$, since:

$$
\begin{equation*}
\mathrm{T}=\rho u_{*}^{2} \tag{1}
\end{equation*}
$$

$\qquad$
Shear stress $\tau$ is defined as the rate of momentum transfer per unit area during a given time. $u_{*}$ is the Turbulence velocity, which is a disturbance in wind speed caused by an external force. The result of the change is either in the horizontal or vertical direction, which means:

$$
\begin{equation*}
u_{*}=u^{\prime}=w^{\prime} \tag{2}
\end{equation*}
$$

where $u^{\prime}$ and $w$ ' are the turbulent velocities in the horizontal and vertical directions, respectively.
$u_{*}$ can be calculated using the log wind profile equation:

$$
\begin{equation*}
\ln (\mathrm{z})=\frac{\mathrm{k}}{\mathrm{u} *} u(z)+\ln z_{\circ} . \tag{3}
\end{equation*}
$$

Where the relationship between $u(z)$ on the $x$ axis and $\ln (z)$ on the $y$ axis is a linear relationship so the formula of straight line $(y=a+b x)$ can be similar to equation (3) in the neutral condition. so we can determine $u_{*}$ using slope value as shown :

$$
\begin{equation*}
u_{*}=\frac{\mathrm{k}}{\text { slope }} \ldots \tag{4}
\end{equation*}
$$

Where
k : is the (Von Karman) constant and its value $\mathrm{k}=(0.4)$.
in the same way the roughness length $Z_{\circ}$ can be determined using equation below :

$$
\begin{equation*}
z_{\circ}=\exp (a) \ldots \ldots \ldots \tag{5}
\end{equation*}
$$

Where (a) is the intercept in Z-axis.

## methodology:

1- Turn on the wind tunnel.
2- Record the wind speed using Hot-wire anemometer for different heights (every 2.5 cm .).

3- Record the data as in the following table:

| freq | $\mathrm{Z}(\mathrm{m})$ | $\ln (\mathrm{z})$ | $\mathrm{u}(\mathrm{m} / \mathrm{s})$ | $\mathrm{u}^{2}$ | $\operatorname{Ln} \mathrm{Z} \times \mathrm{u}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 0.025 |  |  |  |  |
| 2 | 0.05 |  |  |  |  |
| 3 | 0.075 |  |  |  |  |
| 4 | 0.1 |  |  |  |  |
| 5 | 0.125 |  |  |  |  |
| 6 | 0.15 |  |  |  |  |
| 7 | 0.175 |  |  |  |  |
| 8 | 0.2 |  |  |  |  |
| 9 | 0.225 |  |  |  |  |
| 10 | 0.25 |  |  |  |  |
| $\mathrm{n}=10$ |  | $\sum \operatorname{Ln}(\mathrm{Z})$ | $\sum \mathrm{u}$ | $\sum \mathrm{u}^{2}$ | $\sum \operatorname{Ln} \mathrm{Z} \times \mathrm{u}$ |

4- Draw the linear regression between $u(z)$ on the $(x)$ axis and $\ln (z)$ on the (y) axis.

5- Extract the slope value from the graph or through the relationship:

$$
\text { slope }=\frac{\sum \ln z u(z)-\left(\frac{\left(\sum u(z)\right)\left(\sum \ln z\right)}{n}\right)}{\sum\left(u_{(z)}^{2}\right)-\frac{\left(\sum u(z)\right)^{2}}{n}}
$$

where: n is the number of Record.

Then calculate the $u_{*}$ value from equation (4).
6- calculate the value of intercept (a) from the formula below:

$$
a=\text { ave }(\ln z)-\text { slope } *(\text { ave } u(z))
$$

whereas:
ave $(\ln z)$ : is the rate of $\ln z$.
slope : is the slope of a straight line.
ave $u(z)$ : the average of recorded wind speed.
7- calculate the value of $\mathrm{Z}_{\circ}$ through equation No (5).
