

Chapter three * Mathematics

Modular Arithmetic *

several important cryptosystems make use of modular arithmetic. This is *
when the answer to a calculation is always in the range $0 - m$ where m is
the modulus.

$(a \bmod n)$ means the remainder when a is divided by n . *

$$a \bmod n = r *$$

$$a \operatorname{div} n = q *$$

$$a = qn + r *$$

$$r = a - q * n *$$

Example :- if $a=13$ and $n=5$, find q and r .

$q=13 \operatorname{div} 5=2$ and $r=13-2 * 5=3$ which is equivalent to $(13 \bmod 5)$

Example :- find $(-13 \bmod 5)$.

This can be found by find the number (b) where $5*b > 13$ then let $b=3$ and
 $5*3=15$ which is less than 13 so

$$-13 \bmod 5 = 5*3 - 13 = 2$$

Properties of Congruences.*

Two numbers a and b are said to be “congruent modulo n ” if*

$$(a \bmod n) = (b \bmod n) \rightarrow a \equiv b \pmod{n}$$

The difference between a and b will be a multiple of n So $a-b$ *
 $= kn$ for some value of k

Examples $4 \equiv 9 \equiv 14 \equiv 19 \equiv -1 \equiv -6 \pmod{5}$ *

$$73 \equiv 4 \pmod{23}$$

Properties of Modular Arithmetic.*

$$[(a \bmod n) + (b \bmod n)] \bmod n = (a + b) \bmod n. \text{ } ^1$$

$$[(a \bmod n) - (b \bmod n)] \bmod n = (a - b) \bmod n. \text{ } ^2$$

$$[(a \bmod n) \times (b \bmod n)] \bmod n = (a \times b) \bmod n. \text{ } ^3$$

$$11 \bmod 8 = 3; 15 \bmod 8 = 7$$

$$[(11 \bmod 8) + (15 \bmod 8)] \bmod 8 = 10 \bmod 8 = 2$$

$$(11 + 15) \bmod 8 = 26 \bmod 8 = 2$$

$$[(11 \bmod 8) - (15 \bmod 8)] \bmod 8 = -4 \bmod 8 = 4$$

$$(11 - 15) \bmod 8 = -4 \bmod 8 = 4$$

$$[(11 \bmod 8) \times (15 \bmod 8)] \bmod 8 = 21 \bmod 8 = 5$$

$$(11 \times 15) \bmod 8 = 165 \bmod 8 = 5$$

Exponentiation is done by repeated multiplication, as in ordinary arithmetic. *

Example *

To find $(11^7 \bmod 13)$ do the followings

$$11^2 = 121 \equiv 4 \pmod{13}$$

$$11^4 = (11^2)^2 \equiv 4^2 \equiv 3 \pmod{13}$$

$$11^7 \equiv 11 \times 4 \times 3 \equiv 132 \equiv 2 \pmod{13}$$

Greatest Common Divisor(GCD).*

Let a and b be two non-zero integers. The greatest common divisor of a and b , denoted $\gcd(a,b)$ is the largest of all common divisors of a and b .

When $\gcd(a,b) = 1$, we say that a and b are *relatively prime*.

It can be calculated using the following equation: -

$$\mathbf{GCD(a,b)=GCD(b,a \bmod b)}$$

Example :- find the $\text{GCD}(72,48)$.

$$\text{GCD}(89,25)=\text{GCD}(25, 89 \bmod 25)= \text{GCD}(25, 14)$$

$$\text{GCD}(25, 14)=\text{GCD}(14, 25 \bmod 14)= \text{GCD}(14,11)$$

$$\text{GCD}(14,11)=\text{GCD}(11, 14 \bmod 11)= \text{GCD}(11,3)$$

$$\text{GCD}(11,3)=\text{GCD}(3, 11 \bmod 3)=\text{GCD}(3, 2)$$

$$\text{GCD}(3,2)=\text{GCD}(2, 3 \bmod 2)=\text{GCD}(2,1)$$

$$\text{GCD}(2,1)=\text{GCD}(1, 2 \bmod 1)=\text{GCD}(1,0) \quad \text{so the } \text{GCD}(89,25)=1$$

Least Common Multiple (LCM). *

The least common multiple of the positive integers a and b is the smallest positive integer that is divisible by both a and b. *

The least common multiple of a and b is denoted by $LCM(a, b)$. *

It can be calculated using the following equation: -•

$$LCM(a, b) = |a * b| / GCD(a, b)$$

Example :- find the $LCM(354, 144)$. *

$$GCD(354, 144) = GCD(144, 354 \bmod 144) = GCD(144, 66)$$

$$GCD(144, 66) = GCD(66, 144 \bmod 66) = GCD(66, 12)$$

$$GCD(66, 12) = GCD(12, 66 \bmod 12) = GCD(12, 6)$$

$$GCD(12, 6) = GCD(6, 12 \bmod 6) = GCD(6, 0) = 6$$

$$LCM(354, 143) = (354 * 144) / 6 = 8496$$

In Z_n , two numbers a and b are the multiplicative inverse of each other if

$$a \times b \equiv 1 \pmod{n}$$

The extended Euclidean algorithm finds the multiplicative inverses of b in Z_n when n and b are given and $\gcd(n, b) = 1$ as

~~Multiplicative inverse in this figure:~~

a. Process

```

 $r_1 \leftarrow n; \quad r_2 \leftarrow b;$ 
 $t_1 \leftarrow 0; \quad t_2 \leftarrow 1;$ 

while ( $r_2 > 0$ )
{
   $q \leftarrow r_1 / r_2;$ 

   $r \leftarrow r_1 - q \times r_2;$ 
   $r_1 \leftarrow r_2; \quad r_2 \leftarrow r;$ 

   $t \leftarrow t_1 - q \times t_2;$ 
   $t_1 \leftarrow t_2; \quad t_2 \leftarrow t;$ 
}

if ( $r_1 = 1$ ) then  $b^{-1} \leftarrow t_1$ 
  
```

b. Algorithm

Example: - Find the multiplicative inverse of 11 in Z_{26} .*

The $\text{GCD}(26,11)$ must be 1 in order to find the inverse. Bu using*
the extended Euclidean algorithm, we can use this table

q	r_1	r_2	r	t_1	t_2	t
2	26	11	4	0	1	-2
2	11	4	3	1	-2	5
1	4	3	1	-2	5	-7
3	3	1	0	5	-7	26
	1	0		-7	26	

-7 mod 26=19.*

the equation •

$$n = qn + r$$

Example: - Find the multiplicative inverse of 11 in Z_{26} . *

- $26 = 11 \cdot 2 + 4$

- $\swarrow \searrow$ $11 = 4 \cdot 2 + 3$

- $4 = 3 \cdot 1 + 1$

- $\swarrow \searrow$ $3 = 3 \cdot 1 + 0$

- We are now in reverse compensation starting from one as shown

- $1 = 4 - (3 \cdot 1)$

- $1 = 4 - (11 - (4 \cdot 2))$

- $1 = \underline{4} - 11 + \underline{4 \cdot 2}$

- $1 = 3 \cdot 4 - 11$

- $1 = 3 \cdot (26 - 11 \cdot 2) - 11$

- $1 = 3 \cdot 26 - 6 \cdot 11 - 11 = 3 \cdot 26 - \underline{7} \cdot 11$ so the multiplicative inverse of 11 is -7

Example :- Find the multiplicative inverse of 23 in Z_{100} . *

$$100 = 23 \cdot 4 + 8 *$$

$$23 = 8 \cdot 2 + 7 *$$

$$8 = 7 \cdot 1 + 1 *$$

$$7 = 1 \cdot 7 + 0 *$$

Now in revers way *

$$1 = 8 - (7 \cdot 1) *$$

$$1 = 8 - (23 - 8 \cdot 2) *$$

$$1 = 8 - 23 + 8 \cdot 2 *$$

$$1 = 3 \cdot 8 - 23 *$$

$1 = 3 \cdot (100 - 23 \cdot 4) - 23 = 3 \cdot 100 - 12 \cdot 23 - 23 = 3 \cdot 100 - \underline{13} \cdot 23$ So the multiplicative inverse of 23 in Z_{100} is -23 or 87 (-23 mod 100). *
