

Computer Memory

- ✚ The memory of a computer is where the program and data are stored before the calculations begin.
- ✚ The memory is equivalent to thousands of registers, each storing a binary word.
- ✚ **Registers** : can be made from basic logic gates to store, a binary value.
- ✚ **Registers** are fast stand-alone storage locations that hold data temporarily. **The main types of registers are :**
 - **Data Registers (R1, ...R3)** hold intermediate results to speed up operations.
 - **Instruction register (I)** holds one fetched instruction from memory to be executed after interpretation.
 - **Program Counter (PC) registers** point (تؤشر) to the address of the next instruction in memory to be executed. See figure 1.

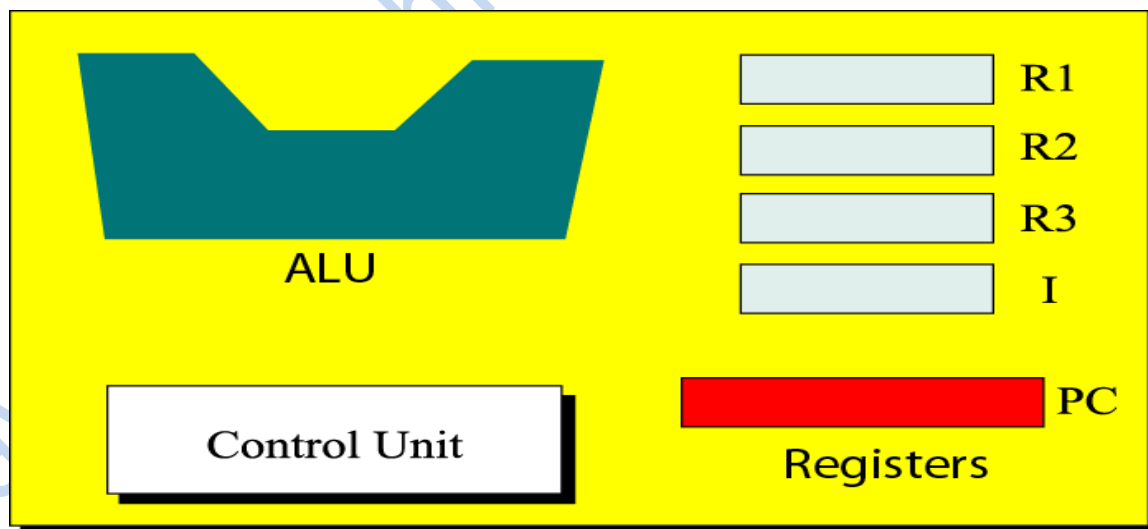

Figure 1: CPU Structure

- ✚ **Main memory** is a collection of storage location, each with a unique identifier called address.
- ✚ **A program (data & Instructions)** should be stored in memory in order to get executed.
- ✚ The total number of uniquely identifiable locations in memory is called **address space**.

Memory units

<i>Unit</i>	<i>Number of bytes</i>
Kilobyte	2^{10} bytes
Megabyte	2^{20} bytes
Gigabyte	2^{30} bytes
Terabyte	2^{40} bytes
Petabyte	2^{50} bytes

- ✚ Memory locations and addresses determine how the computer's memory is organized so that the user can efficiently store or retrieve information from the computer.
- ✚ The computer's memory is made of a silicon chip which has millions of storage cell, where each storage cell is capable to store a bit of information which value is either 0 or 1.
- ✚ But the fact is, **computer memory holds instructions and data**, and a single bit is very small to hold this

information so bits are rarely (نادرا) used individually. As a solution to this, the bits are grouped in fixed sizes of **n bits**.

- Each byte is given a unique numeric address, which represents its location just as a street address represents the location of a house,
- The group of **n bit** is termed as word where n is termed as the word length. General-purpose computers nowadays have 32 to 64 bits. See figure 2.

Figure 2 :

Memory Words

- Data are written into memory and readout of memory, based on their address.
- Now, whenever you want to store any instruction or data may it be of a byte or a word **you have to access a memory location**.

NOT: The memory locations are addressed from 0 to 2^K-1 i.e. a memory has 2^K addressable locations. And thus the address space of the computer has 2^K addresses.

- Figure 3 diagrams a section of memory. Note that the first word of data has a decimal value of (01111001=121 decimal) and an address of 0000.

	Addresses	Values
• Because computers operate by storing numbers as bit pattern, the address is also represented as bit pattern	0000000000000000	01111001
• Address starts from 0 to last addressable word in address space.	0000000000000001	10010100
• To address 64 kB (2^{16}) of memory, you need to use 16 bit for addressing.	0000000000000010	10000000
	•	•
	•	•
	•	•
	1111111111111101	11110000
	1111111111111110	11100000
	1111111111111111	00000111
	Memory	

Figure 3:A section of memory

Memory addressing Size

The size of the address bus indicates the maximum addressable number of bytes. Table 1 shows the size of addressable memory for a given address bus size. For example:

Table 1. Addressable memory (in bytes) related to address bus size

✓ A 1-bit address bus can address up to two locations (that is 0 and 1).	Address bus size	Addressable memory (bytes)
	1	2
✓ A 2-bit address bus can address 2^2 or 4 locations (that is 00, 01, 10 and 11).	2	4
	3	8
	4	16
	5	32
	6	64
✓ A 20-bit address bus can address up to 2^{20} addresses (1 MB).	7	128
	8	256
	9	512
	10	1K*
	14	16K
✓ A 24-bit address bus can address up to 16 MB.	15	32K
	16	64K
	17	128K
	18	256K
	19	512K
✓ A 32-bit address bus can address up to 4 GB.	20	1M [†]
	21	2M
	22	4M
	23	8M
	24	16M
	25	32M
	26	64M
	32	4G [‡]
	64	16GG

**NOT**

In general, if a computer has N words of memory, you need an unsigned integer of size $\log_2 N$ to refer to each memory location.

Example: How many address inputs are required to access 256 bytes memory?

Solution:

Here , the memory size is 256 bytes

$$2^K = 256 \rightarrow 2^K = 2^8 \rightarrow K=8 \text{ bits (address bus)}$$

Example: How many address lines are required to access 16 KB of memory size?

Solution:

Here , the memory size is 16 KB

$$2^K = 16 \text{ KB} \rightarrow 2^K = 16 \times 1 \text{ KB} \rightarrow 2^K = 2^4 \times 1 \text{ KB}$$

$$2^K = 2^4 \times 2^{10}$$

$$K=14 \text{ bits (address bus)}$$

Example: the number of bits needed to address 4KB are -----

Solution:

Address Space

What is address space with example?

A computer's address space is the total amount of memory that can be addressed by the computer. The term may refer to the physical memory (RAM chips). For example, a 32-bit computer can address 4GB of physical memory.

Memory Space

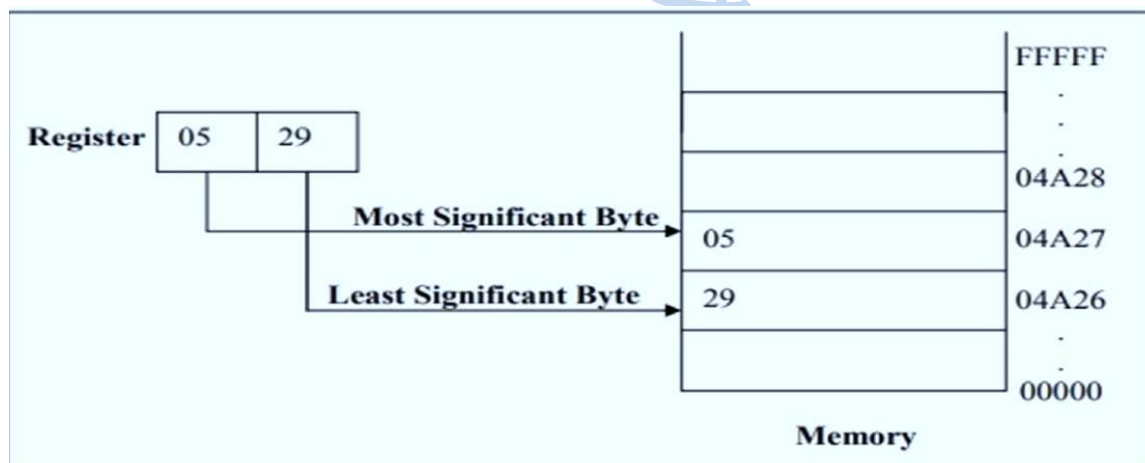

What is address and memory space ? explain?

An address space is a range of valid addresses in memory that are available for a program or process. That is, it is the memory that a program or process can access. The memory can be used for executing instructions and storing.

Addressable Memory

- Computers usually have two kinds of addressable memory:
The first **is random access memory (RAM)**, which allows the computer to read and write data at any of its addresses (it is also called **read/write memory or RWM**).
- All data in this type of memory **are lost** when the power is turned off and is called volatile memory (ذاكرة غير مستقرة أو متطايرة).
- The second type of memory is **read-only memory (ROM)**, which is similar to RAM except that new data cannot be written in; all data in ROM are loaded at the factory and cannot be changed by the computer.
- This memory does not lose its data when power is turned off and is called non-volatile memory,
- Most microprocessor systems have both RAM and ROM. **RAM is used for temporary program storage**
- **ROM** is used to store programs and data that need to be always available.

- Depending on the model, the processor can access one or more bytes of memory at a time.
- Consider the Hexa value (**0529H**) which requires two bytes or one word of memory. It consists of high order (**most significant**) byte **05** and a low order (**least significant**) byte **29**.
- The processor stores the data in memory in reverse byte sequence i.e. the low order byte in the low memory address and the high order byte in the high memory address. For example, the processor transfers the value **0529H** from a register into memory address **04A26 H** and **04A27H** as shown below:

- The processor expects numeric data in memory to be in reverse byte sequence and processes the data accordingly, again reversing the bytes, restoring them to correctly in the register as **hexa 0529H**. When programming in assembly language, you have to distinguish between the address of a memory location and its contents. In the above example the content of address **04A26H** is **29**, and the content of address **04A27H** is **05**.
